

Types of Golf Discs

There are 4 primary categories for golf discs, each of which is identified by rim profile characteristics that determine relative speed and distance capability(ies). **The most influential variant in speed is the rim width.** Lower speeds are generally better for short range, and higher speeds are generally better for longer range.

DISTANCE DRIVER (approximate range = 300' +)
Very sleek, sharp edged golf discs, usually with rims in the 20-26mm width range. A Distance Driver is generally suitable for very long range shots, and may be more difficult to launch & control with consistency.

FAIRWAY DRIVER (approximate range = 200' - 400')
Round edged to sharp edged golf discs, usually with rims in the 15-20mm width range. A Fairway Driver is generally suitable for medium to long range shots, and may be easier to launch & control with consistency.

MULTI-PURPOSE (approximate range = 100' - 300')
Dull edged to round edged golf discs, usually with rims in the 10-15mm width range. A Multi-Purpose is generally suitable for short to medium range shots, and may be favored for versatility & accuracy to the pin on long or windy putts.

PUTT & APPROACH (approximate range = 0' - 200')
Flat edged to dull edged golf discs, usually with rims in the 2-10mm width range. A Putt & Approach is generally suitable for all short range shots, and may be preferred for slower flights with finesse.

The **Universal Stability Guide™** establishes industry benchmarks to generalize the basic flight of a golf disc, based on a 'full-speed' release and clockwise revolution. Individual characteristics can be quite complex, and there are many variables which effect performance, but the USG™ provides a standard reference to compare stability for all types of discs.

STABILITY RATING DESCRIPTIONS

USG [+1] golf discs are designed to fly with some hyzer (approximately 10° over stable) when released with the balanced form and power of an experienced player. This level of stability is well suited for big backhands, long S-curve anhyzers, moderate head wind conditions, sidearm draws, and skipshots.
* This level of stability may be more appropriate for experienced players.

USG [0] golf discs are designed to fly level and straight (approximately stable) when released with the balanced form and power of an experienced player. This level of stability is well suited for accuracy, control, and diverse shot selections.
* Beginner players may need to release the disc intentionally angled with 'anhyzer', or simply aim to the right, because the disc will curl back to the left at slower speeds.

USG [-1] golf discs are designed to fly with some anhyzer (approximately 10° under stable) when released with the balanced form and power of an experienced player. This level of stability is well suited for shots which break gently to the right, downwind conditions, or for low-turnover rollers.
* This level of stability may also be good for beginners developing flight control.
